

# MyDeliveryProperties Module

---

Module dedicated to configuration property assembly, packaging environment-specific properties for deployment.

## Purpose

---

- Centralizes application property files (e.g., system parameters, external endpoint URLs, credentials placeholders, feature toggles).
- Provides assembly scripts/resources to integrate properties into deployable EAR/WAR artifacts.

## Structure

---

- `Assembly/InstallScripts` : Deployment scripts (Python) that likely inject or validate property sets.
- `Assembly/PlaceholderFiles` : Template property files included for environments.
- `Properties` : (Not listed here, expected) actual .properties files for different locales/environments.

## Typical Responsibilities

---

- Maintain consistent naming across environments (DEV/TEST/PROD) for keys consumed by `DefaultMyDeliveryServiceBase` and helpers.
- Provide versioned changes tracked by parent build (Maven filtering may inject build properties).

## Extension

---

- To add new property: define in appropriate environment file and document in README or change log; update service layer to read via `Properties` loader.
- Sensitive values should be externalized (e.g., via environment variables or secure vault) and only placeholders stored here.
